HYDROCARBONS

$$\begin{array}{ccc} C_{2}H_{5}-Cl &+ H_{2} \xrightarrow{Zn, H^{+}} & C_{2}H_{6} + HCl \\ Chloroethane & Ethane & (13.5) \\ CH_{3}CH_{2}CH_{2}Cl + H_{2} \xrightarrow{Zn, H^{+}} & CH_{3}CH_{2}CH_{3} + HCl \\ 1-Chloropropane & Propane \\ & & & & & & \\ \end{array}$$

 ii) Alkyl halides on treatment with sodium metal in dry ethereal (free from moisture) solution give higher alkanes. This reaction is known as **Wurtz reaction** and is used for the preparation of higher alkanes containing even number of carbon atoms.

 $CH_3Br+2Na+BrCH_3 \xrightarrow{dry ether} CH_3 - CH_3 + 2NaBr$ Bromomethane Ethane (13.7)

 $\begin{array}{c} C_2H_5Br+2Na+BrC_2H_5 \xrightarrow{dry \ ether} C_2H_5 - C_2H_5 \\ Bromoethane & n-Butane \\ (13.8) \end{array}$

What will happen if two different alkyl halides are taken?

3. From carboxylic acids

i) Sodium salts of carboxylic acids on heating with soda lime (mixture of sodium hydroxide and calcium oxide) give alkanes containing one carbon atom less than the carboxylic acid. This process of elimination of carbon dioxide from a carboxylic acid is known as **decarboxylation**.

 $CH_3COO^-Na^+ + NaOH \xrightarrow{CaO} CH_4 + Na_2CO_3$ Sodium ethanoate

Problem 13.6

Sodium salt of which acid will be needed for the preparation of propane ? Write chemical equation for the reaction.

Solution

Butanoic acid, $CH_3CH_2CH_2COO^-Na^+ + NaOH \xrightarrow{CaO}$ $CH_3CH_2CH_3 + Na_2CO_3$

ii) **Kolbe's electrolytic method** An aqueous solution of sodium or potassium salt of a carboxylic acid on electrolysis gives alkane

containing even number of carbon atoms at the anode.

 $2CH_3COO^-Na^+ + 2H_2O$ Sodium acetate

↓Electrolysis

$$CH_3 - CH_3 + 2CO_2 + H_2 + 2NaOH$$
 (13.9)

The reaction is supposed to follow the following path :

i)
$$2CH_3COO^-Na^+ \rightleftharpoons 2CH_3 - C - O^- + 2Na^+$$

ii) At anode:

$$\begin{array}{ccc}
O & O \\
|| & || \\
2CH_3 - C - O & \xrightarrow{-2e^-} 2CH_3 - C - O & \xrightarrow{\cdot} 2CH_3 + 2CO_2 \uparrow \\
Acetate ion & Acetate & Methyl free \\
& free radical & radical
\end{array}$$

iii)
$$H_3C + CH_3 \longrightarrow H_3C - CH_3$$

iv) At cathode :

 $H_2O+e^- \rightarrow OH+H$

 $2H \rightarrow H_2^{\uparrow}$

Methane cannot be prepared by this method. Why?

13.2.3 Properties

Physical properties

Alkanes are almost non-polar molecules because of the covalent nature of C-C and C-H bonds and due to very little difference of electronegativity between carbon and hydrogen atoms. They possess weak van der Waals forces. Due to the weak forces, the first four members, C_1 to C_4 are gases, C_5 to C_{17} are liquids and those containing 18 carbon atoms or more are solids at 298 K. They are colourless and odourless. What do you think about solubility of alkanes in water based upon nonpolar nature of alkanes? Petrol is a mixture of hydrocarbons and is used as a fuel for automobiles. Petrol and lower fractions of petroleum are also used for dry cleaning of clothes to remove grease stains. On the basis of this observation, what do you think about the nature of the greasy substance? You are correct if you say that grease (mixture of higher

alkanes) is non-polar and, hence, hydrophobic in nature. It is generally observed that in relation to solubility of substances in solvents, polar substances are soluble in polar solvents, whereas the non-polar ones in non-polar solvents *i.e.*, *like dissolves like*.

Boiling point (b.p.) of different alkanes are given in Table 13.2 from which it is clear that there is a steady increase in boiling point with increase in molecular mass. This is due to the fact that the intermolecular van der Waals forces increase with increase of the molecular size or the surface area of the molecule.

You can make an interesting observation by having a look on the boiling points of three isomeric pentanes viz., (pentane, 2-methylbutane and 2,2-dimethylpropane). It is observed (Table 13.2) that pentane having a continuous chain of five carbon atoms has the highest boiling point (309.1K) whereas 2,2 – dimethylpropane boils at 282.5K. With increase in number of branched chains, the molecule attains the shape of a sphere. This results in smaller area of contact and therefore weak intermolecular forces between spherical molecules, which are overcome at relatively lower temperatures.

Chemical properties

As already mentioned, alkanes are generally inert towards acids, bases, oxidising and reducing agents. However, they undergo the following reactions under certain conditions.

1. Substitution reactions

One or more hydrogen atoms of alkanes can be replaced by halogens, nitro group and sulphonic acid group. **Halogenation** takes place either at higher temperature (573-773 K) or in the presence of diffused sunlight or ultraviolet light. Lower alkanes do not undergo nitration and sulphonation reactions. These reactions in which hydrogen atoms of alkanes are substituted are known as *substitution reactions*. As an example, chlorination of methane is given below:

Halogenation

 $CHCl_3 + Cl_2$ -

$$CH_4 + Cl_2 \xrightarrow{h\nu} CH_3Cl + HCl$$

Chloromethane (13.10)

$$CH_3Cl + Cl_2 \xrightarrow{h\nu} CH_2Cl_2 + HCl$$

Dichloromethane (13.11)

$$CH_2Cl_2 + Cl_2 \xrightarrow{h\nu} CHCl_3 + HCl$$

Trichloromethane (13.12)

 \rightarrow CCl₄ + HCl Tetrachloromethane (13.13)

Molecular formula	Name	Molecular mass/u	b.p./(K)	m.p./(K)
CH4	Methane	16	111.0	90.5
$C_2 H_6$	Ethane	30	184.4	101.0
C ₃ H ₈	Propane	44	230.9	85.3
C_4H_{10}	Butane	58	272.4	134.6
C_4H_{10}	2-Methylpropane	58	261.0	114.7
C ₅ H ₁₂	Pentane	72	309.1	143.3
$C_{5}H_{12}$	2-Methylbutane	72	300.9	113.1
$C_{5}H_{12}$	2,2-Dimethylpropane	72	282.5	256.4
$C_{6}H_{14}$	Hexane	86	341.9	178.5
$C_7 H_{16}$	Heptane	100	371.4	182.4
C ₈ H ₁₈	Octane	114	398.7	216.2
$C_{9}H_{20}$	Nonane	128	423.8	222.0
$C_{10}H_{22}$	Decane	142	447.1	243.3
$C_{20}H_{42}$	Eicosane	282	615.0	236.2

Table 13.2 Variation of Melting Point and Boiling Point in Alkanes

380

HYDROCARBONS

$$CH_3-CH_3 + Cl_2 \xrightarrow{h\nu} CH_3-CH_2Cl + HCl$$

Chloroethane (13.14)

It is found that the rate of reaction of alkanes with halogens is $F_2 > Cl_2 > Br_2 > I_2$. Rate of replacement of hydrogens of alkanes is : $3^\circ > 2^\circ > 1^\circ$. Fluorination is too violent to be controlled. Iodination is very slow and a reversible reaction. It can be carried out in the presence of oxidizing agents like HIO₃ or HNO₃.

$$CH_4 + I_2 \rightleftharpoons CH_3 I + HI$$
 (13.15)

$$\mathrm{HIO}_{3} + 5\mathrm{HI} \rightarrow 3\mathrm{I}_{2} + 3\mathrm{H}_{2}\mathrm{O} \tag{13.16}$$

Halogenation is supposed to proceed via free radical chain mechanism involving three steps namely initiation, propagation and termination as given below:

Mechanism

(i) *Initiation* : The reaction is initiated by homolysis of chlorine molecule in the presence of light or heat. The Cl–Cl bond is weaker than the C–C and C–H bond and hence, is easiest to break.

$$Cl-Cl \xrightarrow{h\nu} Cl + Cl$$

Chlorine free radicals

(ii) **Propagation**: Chlorine free radical attacks the methane molecule and takes the reaction in the forward direction by breaking the C-H bond to generate methyl free radical with the formation of H-Cl.

(a)
$$CH_4 + \dot{Cl} \xrightarrow{h\nu} \dot{CH}_3 + H - Cl$$

The methyl radical thus obtained attacks the second molecule of chlorine to form $CH_3 - Cl$ with the liberation of another chlorine free radical by homolysis of chlorine molecule.

(b)
$$CH_3 + Cl - Cl \xrightarrow{hv} CH_3 - Cl + Cl$$

Chlorine
free radical

The chlorine and methyl free radicals generated above repeat steps (a) and (b) respectively and thereby setup a chain of reactions. The propagation steps (a) and (b) are those which directly give principal products, but many other propagation steps are possible and may occur. Two such steps given below explain how more highly haloginated products are formed.

$$\begin{array}{l} \mathrm{CH}_{3}\mathrm{Cl} + \mathrm{Cl} \ \rightarrow \mathrm{CH}_{2}\mathrm{Cl} \ + \mathrm{HCl} \\ \dot{\mathrm{CH}}_{2}\mathrm{Cl} \ + \mathrm{Cl} - \mathrm{Cl} \ \rightarrow \mathrm{CH}_{2}\mathrm{Cl}_{2} \ + \dot{\mathrm{Cl}} \end{array}$$

(iii) *Termination:* The reaction stops after some time due to consumption of reactants and / or due to the following side reactions :

The possible chain terminating steps are :

(a)
$$Cl + Cl \rightarrow Cl-Cl$$

(b) $H_3C + CH_3 \rightarrow H_3C-CH_3$

(c)
$$H_3C + Cl \rightarrow H_3C-Cl$$

Though in (c), $CH_3 - Cl$, the one of the products is formed but free radicals are consumed and the chain is terminated. The above mechanism helps us to understand the reason for the formation of ethane as a byproduct during chlorination of methane.

2. Combustion

Alkanes on heating in the presence of air or dioxygen are completely oxidized to carbon dioxide and water with the evolution of large amount of heat.

$$\begin{array}{rcl} \mathrm{CH}_4(\mathrm{g}) + 2\mathrm{O}_2(\mathrm{g}) &\to & \mathrm{CO}_2(\mathrm{g}) + 2\mathrm{H}_2\mathrm{O}(\mathrm{l}); \\ & & & & \Delta_{\mathrm{c}}H^{\ominus} = & 890 \, \mathrm{kJ} \, \mathrm{mol}^{-1} \\ & & & & & (13.17) \\ \mathrm{C}_4\mathrm{H}_{10}(\mathrm{g}) + & & & & & & & \\ \mathrm{C}_4\mathrm{H}_{10}(\mathrm{g}) + & & & & & & & & \\ \mathrm{C}_4\mathrm{H}_{10}(\mathrm{g}) + & & & & & & & & \\ \mathrm{C}_4\mathrm{H}_{10}(\mathrm{g}) + & & & & & & & & \\ \mathrm{C}_4\mathrm{H}_{10}(\mathrm{g}) + & & & & & & & & \\ \mathrm{C}_4\mathrm{H}_{10}(\mathrm{g}) + & & & & & & & \\ \mathrm{C}_4\mathrm{H}_{10}(\mathrm{g}) + & & & & & & \\ \mathrm{C}_4\mathrm{H}_{10}(\mathrm{g}) + & & & & & & \\ \mathrm{C}_4\mathrm{H}_{10}(\mathrm{g}) + & & & & & & \\ \mathrm{C}_4\mathrm{H}_{10}(\mathrm{g}) + & & & \\ \mathrm{C}_4\mathrm{H}_{10}(\mathrm{g}) + & & \\ \mathrm{C}_4\mathrm$$

The general combustion equation for any alkane is :

$$C_n H_{2n+2} + \left(\frac{3n+1}{2}\right) O_2 \rightarrow nCO_2 + (n+1) H_2O$$

(13.19)

Due to the evolution of large amount of heat during combustion, alkanes are used as fuels.

During incomplete combustion of alkanes with insufficient amount of air or dioxygen, carbon black is formed which is used in the manufacture of ink, printer ink, black pigments and as filters.

CHEMISTRY

$$CH_4(g)+O_2(g) \xrightarrow{\text{Incomplete}} C(s)+2H_2O(l)$$
(13.20)

3. Controlled oxidation

Alkanes on heating with a regulated supply of dioxygen or air at high pressure and in the presence of suitable catalysts give a variety of oxidation products.

(i)
$$2CH_4 + O_2 \xrightarrow{Cu/523K/100atm} 2CH_3OH$$

Methanol
(13.21)

(ii)
$$CH_4 + O_2 \xrightarrow{MO_2O_3} A HCHO + H_2O$$

Methanal

(13.22)

(iii) $2CH_3CH_3 + 3O_2 \xrightarrow{(CH_3COO)_2Mn} 2CH_3COOH$ Ethanoic acid $+ 2H_2O$

(13.23)

(13.24)

(iv) Ordinarily alkanes resist oxidation but alkanes having tertiary H atom can be oxidized to corresponding alcohols by potassium permanganate.

 $\begin{array}{ccc} (CH_3)_3 CH & \xrightarrow{KMnO_4} & (CH_3)_3 COH \\ 2 - Methyl propane & 2 - Methyl propan - 2 - ol \end{array}$

4. Isomerisation

n-Alkanes on heating in the presence of anhydrous aluminium chloride and hydrogen chloride gas isomerise to branched chain alkanes. Major products are given below. Some minor products are also possible which you can think over. Minor products are generally not reported in organic reactions.

$$\begin{array}{c} \mathrm{CH}_{3}(\mathrm{CH}_{2})_{4}\,\mathrm{CH}_{3} \xrightarrow{\mathrm{Anhy.\ AlCl_{3}/HCl}} \\ n-\mathrm{Hexane} \\ \mathrm{CH}_{3}\mathrm{CH}_{-}(\mathrm{CH}_{2})_{2}-\mathrm{CH}_{3}+\mathrm{CH}_{3}\mathrm{CH}_{2}-\mathrm{CH}_{-}\mathrm{CH}_{2}-\mathrm{CH}_{3} \\ & | \\ \mathrm{CH}_{3} & \mathrm{CH}_{3} \\ 2-\mathrm{Methylpentane} & 3-\mathrm{Methylpentane} \\ \end{array}$$

5. Aromatization

n-Alkanes having six or more carbon atoms on heating to 773K at 10-20 atmospheric

pressure in the presence of oxides of vanadium, molybdenum or chromium supported over alumina get **dehydrogenated** and cyclised to benzene and its homologues. This reaction is known as *aromatization* or *reforming*.

Toluene (C_7H_8) is methyl derivative of benzene. Which alkane do you suggest for preparation of toluene ?

6. Reaction with steam

Methane reacts with steam at 1273 K in the presence of nickel catalyst to form carbon monoxide and dihydrogen. This method is used for industrial preparation of dihydrogen gas

$$CH_4 + H_2O \xrightarrow{Ni} CO + 3H_2$$
 (13.27)

7. Pyrolysis

Higher alkanes on heating to higher temperature decompose into lower alkanes, alkenes etc. Such a decomposition reaction into smaller fragments by the application of heat is called *pyrolysis* or *cracking*.

Pyrolysis of alkanes is believed to be a free radical reaction. Preparation of oil gas or petrol gas from kerosene oil or petrol involves the principle of pyrolysis. For example, dodecane, a constituent of kerosene oil on heating to 973K in the presence of platinum, palladium or nickel gives a mixture of heptane and pentene.

 $\begin{array}{ccc} C_{12}H_{26} & \xrightarrow{Pt/Pd/Ni} & C_7H_{16} + & C_5H_{10} + & other \\ Dodecane & Heptane & Pentene & \\ \end{array}$ (13.29)

382

HYDROCARBONS

13.2.4 Conformations

Alkanes contain carbon-carbon sigma (σ) bonds. Electron distribution of the sigma molecular orbital is symmetrical around the internuclear axis of the C-C bond which is not disturbed due to rotation about its axis. This permits free rotation about C-C single bond. This rotation results into different spatial arrangements of atoms in space which can change into one another. Such spatial arrangements of atoms which can be converted into one another by rotation around a C-C single bond are called **conformations** or **conformers** or **rotamers**. Alkanes can thus have infinite number of conformations by rotation around C-C single bonds. However, it may be remembered that rotation around a C-C single bond is not completely free. It is hindered by a small energy barrier of 1-20 kJ mol^{-1} due to weak repulsive interaction between the adjacent bonds. Such a type of repulsive interaction is called torsional strain.

Conformations of ethane : Ethane molecule $(C_{2}H_{e})$ contains a carbon – carbon single bond with each carbon atom attached to three hydrogen atoms. Considering the ball and stick model of ethane, keep one carbon atom stationary and rotate the other carbon atom around the C-C axis. This rotation results into infinite number of spatial arrangements of hydrogen atoms attached to one carbon atom with respect to the hydrogen atoms attached to the other carbon atom. These are called **conformational isomers** (conformers). Thus there are infinite number of conformations of ethane. However, there are two extreme cases. One such conformation in which hydrogen atoms attached to two carbons are as closed together as possible is called eclipsed conformation and the other in which hydrogens are as far apart as possible is known as the staggered conformation. Any other intermediate conformation is called a **skew** conformation.It may be remembered that in all the conformations, the bond angles and the bond lengths remain the same. Eclipsed and the staggered conformations can be represented by Sawhorse and Newman projections.

1. Sawhorse projections

In this projection, the molecule is viewed along the molecular axis. It is then projected on paper by drawing the central C–C bond as a somewhat longer straight line. Upper end of the line is slightly tilted towards right or left hand side. The front carbon is shown at the lower end of the line, whereas the rear carbon is shown at the upper end. Each carbon has three lines attached to it corresponding to three hydrogen atoms. The lines are inclined at an angle of 120° to each other. Sawhorse projections of eclipsed and staggered conformations of ethane are depicted in Fig. 13.2.

2. Newman projections

In this projection, the molecule is viewed at the C–C bond head on. The carbon atom nearer to the eye is represented by a point. Three hydrogen atoms attached to the front carbon atom are shown by three lines drawn at an angle of 120° to each other. The rear carbon atom (the carbon atom away from the eye) is represented by a circle and the three hydrogen atoms are shown attached to it by the shorter lines drawn at an angle of 120° to each other. The Newman's projections are depicted in Fig. 13.3.

Fig. 13.3 Newman's projections of ethane

Relative stability of conformations: As mentioned earlier, in staggered form of ethane, the electron clouds of carbon-hydrogen bonds are as far apart as possible. Thus, there are minimum repulsive forces, minimum energy and maximum stability of the molecule. On the other hand, when the staggered form changes into the eclipsed form, the electron clouds of the carbon - hydrogen bonds come closer to each other resulting in increase in electron cloud repulsions. To check the increased repulsive forces, molecule will have to possess more energy and thus has lesser stability. As already mentioned, the repulsive interaction between the electron clouds, which affects stability of a conformation, is called **torsional** strain. Magnitude of torsional strain depends upon the angle of rotation about C–C bond. This angle is also called **dihedral angle** or torsional angle. Of all the conformations of ethane, the staggered form has the least torsional strain and the eclipsed form, the maximum torsional strain. Therefore, staggered conformation is more stable than the eclipsed conformation. Hence, molecule largely remains in staggered conformation or we can say that it is preferred conformation. Thus it may be inferred that rotation around C-C bond in ethane is not completely free. The energy difference between the two extreme forms is of the order of 12.5 kJ mol^{-1} , which is very small. Even at ordinary temperatures, the ethane molecule gains thermal or kinetic energy sufficient enough to overcome this energy barrier of 12.5 kJ mol⁻¹ through intermolecular collisions. Thus, it can be said that rotation about carbon-carbon single bond in ethane is almost free for all practical purposes. It has not been possible to separate and isolate different conformational isomers of ethane.

13.3 ALKENES

Alkenes are unsaturated hydrocarbons containing at least one double bond. What should be the general formula of alkenes? If there is one double bond between two carbon atoms in alkenes, they must possess two hydrogen atoms less than alkanes. Hence, general formula for alkenes is C_nH_{2n} . Alkenes are also known as olefins (oil forming) since the first member,

ethylene or ethene (C_2H_4) was found to form an oily liquid on reaction with chlorine.

13.3.1 Structure of Double Bond

Carbon-carbon double bond in alkenes consists of one strong sigma (σ) bond (bond enthalpy about 397 kJ mol⁻¹) due to head-on overlapping of sp^2 hybridised orbitals and one weak pi (π) bond (bond enthalpy about 284 kJ mol⁻¹) obtained by lateral or sideways overlapping of the two 2p orbitals of the two carbon atoms. The double bond is shorter in bond length (134 pm) than the C-C single bond (154 pm). You have already read that the pi (π) bond is a weaker bond due to poor sideways overlapping between the two 2p orbitals. Thus, the presence of the pi (π) bond makes alkenes behave as sources of loosely held mobile electrons. Therefore, alkenes are easily attacked by reagents or compounds which are in search of electrons. Such reagents are called electrophilic reagents. The presence of weaker π -bond makes alkenes unstable molecules in comparison to alkanes and thus, alkenes can be changed into single bond compounds by combining with the electrophilic reagents. Strength of the double bond (bond enthalpy, 681 kJ mol⁻¹) is greater than that of a carbon-carbon single bond in ethane (bond enthalpy, 348 kJ mol⁻¹). Orbital diagrams of ethene molecule are shown in Figs. 13.4 and 13.5.

Fig. 13.4 Orbital picture of ethene depicting σ bonds only

13.3.2 Nomenclature

For nomenclature of alkenes in IUPAC system, the longest chain of carbon atoms containing the double bond is selected. Numbering of the chain is done from the end which is nearer to
