

3. Metamerism :-

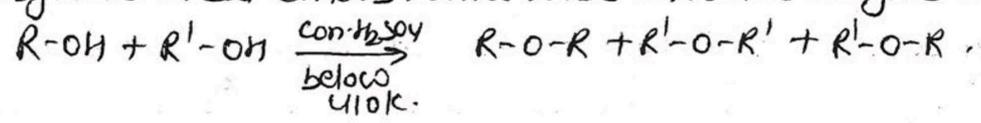

= method of Preparation.

I. Dehydration of alcohol.

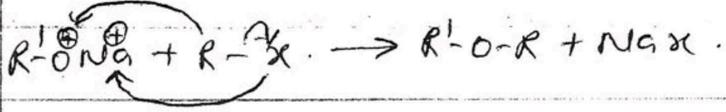

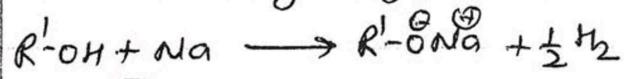

This method is generally not used for the preparation of unsymmetrical ethers. Otherwise mixture may be obtained.

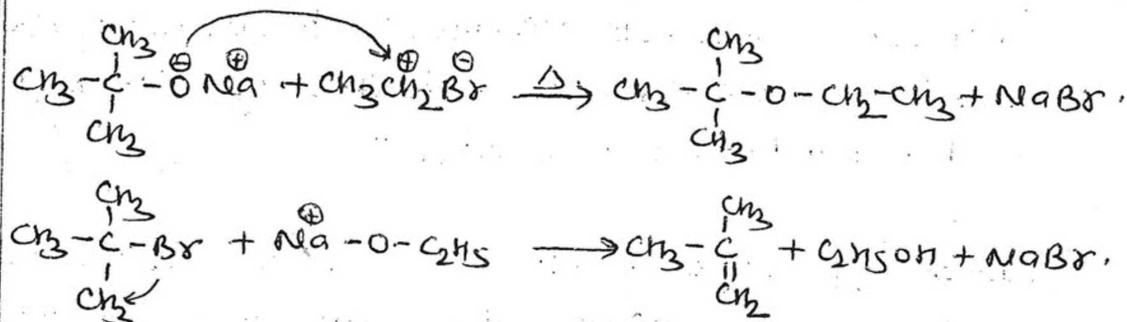

2. From alkyl halide by Williamson's synthesis :-

In laboratory symmetrical and unsymmetrical ethers are prepared by this method. In this method, an alkyl halide is treated with sodium alkoxide prepared from sodium and alcohol. The reaction involves (S_N2) attack of an alkoxide ion on primary alkyl halide.

Note: For preparing unsymmetrical ethers, the halide used should be primary because 2° and 3° halide may form alkene as major products due to elimination process.
 For 2° and 3° alkyl halide, elimination competes over substitution.

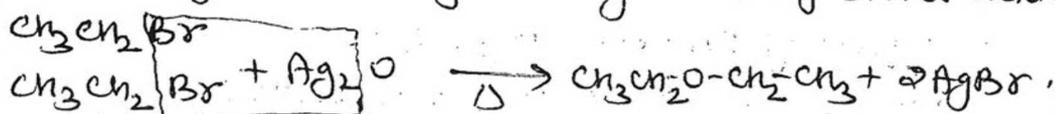

This is because alkoxides are not only nucleophile but strong base also.

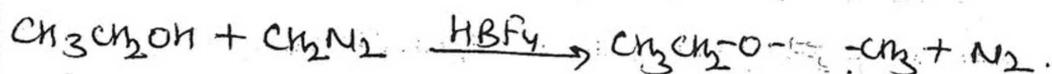

However, aryl halide and sodium alkoxide cannot be used for preparing phenolic ethers because aryl halide are less reactive towards nucleophilic substitution reaction than alkyl halide.

3. From alkyl halides by treating with dry silver oxide —

4. By the action of diazomethane on alcohol —

= Physical Properties.

1. Physical state: — Lower members are gases and higher members are low boiling liquids with pleasant smell.

2. Dipole moment — ether have bent or angular structure with sp^3 hybridisation and greater repulsion in two group as compare

to water molecule so ether have net dipole moment and angle greater than ($109^{\circ}28'$) is 111.7°

3. Boiling Points - ethers have low boiling points and lower than that of isomeric alcohols due to absence of Hydrogen bond and have comparable to those of alkanes of same Carbon numbers - but slightly less.

4. Solubility: The solubility of ethers is comparable to those of corresponding alcohols of the same molecular mass but slightly less.

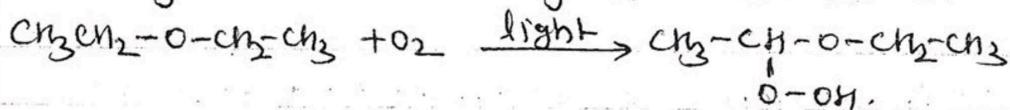

5. Density - All ethers are lighter than water.

= Chemical Properties

Ethers are quite inert and stable compound. They are the least reactive of the functional group. This is because the functional group of ether (-O-) does not contain any active site in their molecule as compared to (-OH) group.

A. Reaction of ethereal oxygen.

1. Action of air (Formation of Peroxide)

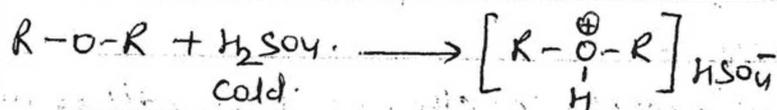

The oxidation occurs at the Carbon atom next to the ethereal oxygen to form hydroperoxide.

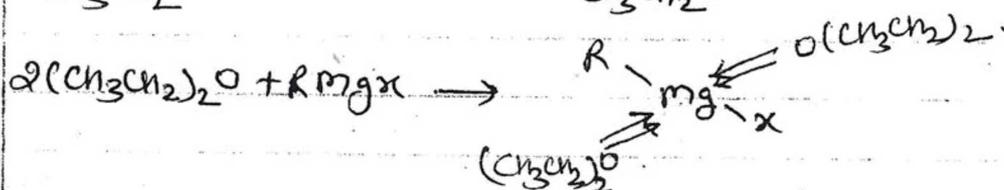

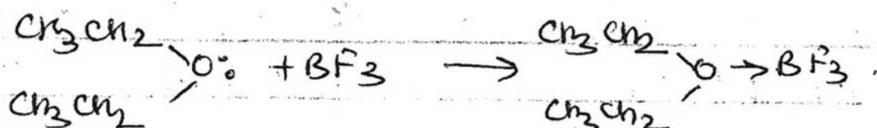

The ether peroxides are reduced to ether and I^- ion is oxidised to I_2 or Fe^{+2} salts are oxidised to Fe^{+3} .

2. Action with Conc. Acids (Formation of oxonium salt)

this test is used to distinguish between ether and alkane because alkane do not react with cold conc. Acids.

3. Reaction with Lewis acids :- Being Lewis base, ethers are form complexes with Lewis acids such as BF_3 , $AlCl_3$, $FeCl_3$ etc. these complexes are called etherates.

Due to the formation of the etherate, Grignard reagent dissolved in ether. So Grignard reagents are usually prepared in ethers. They cannot be prepared in benzene because benzene has no lone pair.

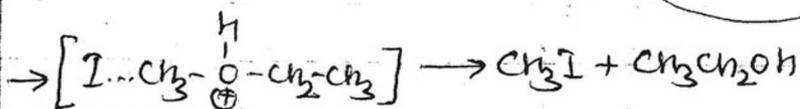

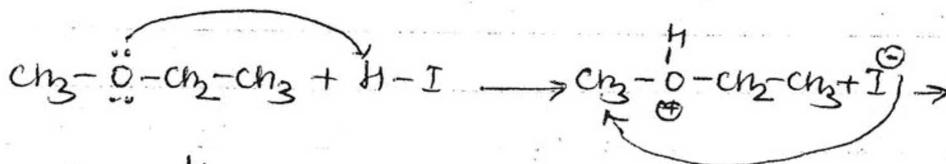

B Reaction Involving C-O bond. —

Carbon-oxygen bond in ethers can be cleaved under drastic condition.

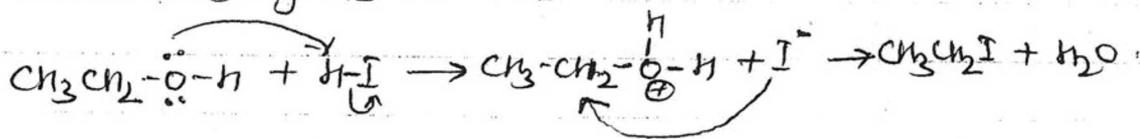

⊥ Cleavage by halogen acids :-

mech.

when excess of HI

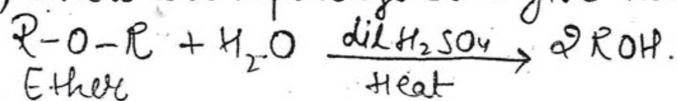

order of reactivity

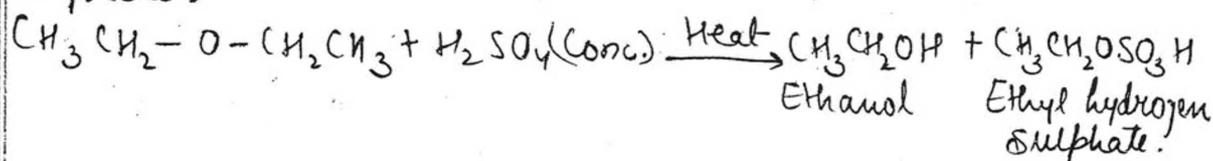

O-CH₃ is weaker than the bond between O-C₆H₅ because the carbon of phenyl is sp² hybridised. Therefore, the attack of halide ion breaks O-CH₃ bond to form CH₃-I. It may be noted that phenol does not react further to give halides because the sp² hybridised carbon of phenyl does not undergo nucleophilic substitution reactions.

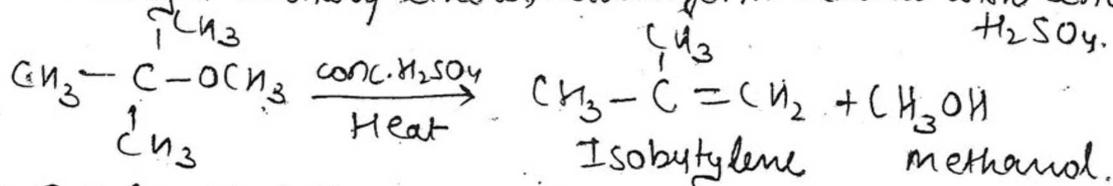

2. Cleavage by Sulphuric Acid: - On heating with dil H₂SO₄ under pressure, ethers are hydrolysed to give alcohols.

If conc. H₂SO₄ is used, ethers form alcohols & ethyl hydrogen sulphates.

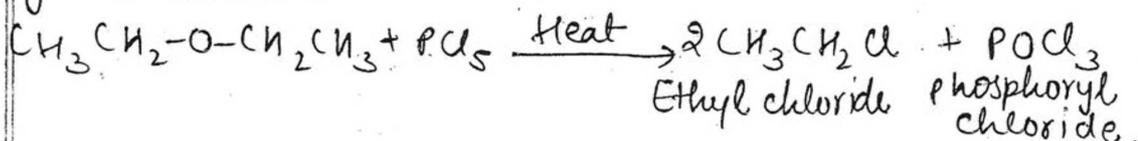

Secondary & tertiary ethers, however form alkenes with conc. H₂SO₄.

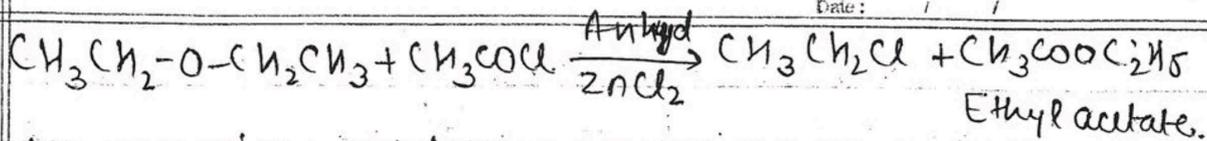

tert-Butyl methyl ether

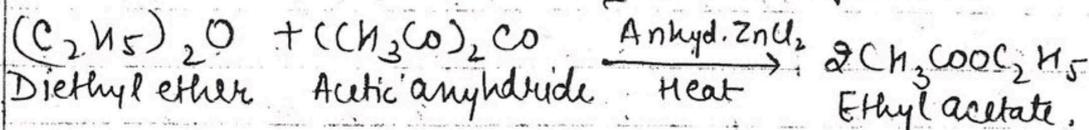

3. Cleavage with phosphorus pentachloride: - Ethers react with PCl₅ on heating to form alkyl chlorides as a result of cleavage of C-O bond.

4. Cleavage by acid chlorides: - Ethers react with acetyl chloride in the presence of anhydrous ZnCl₂ to give alkyl halide and esters.

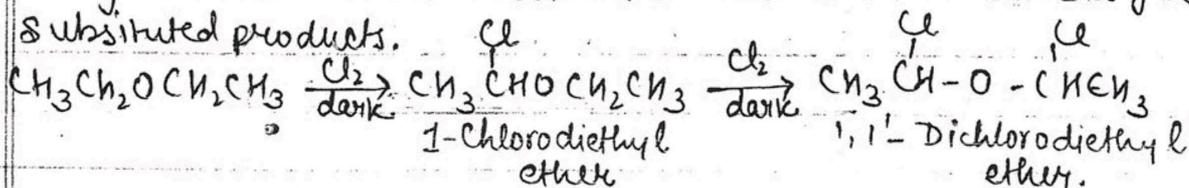

However with anhydrides only esters are formed.

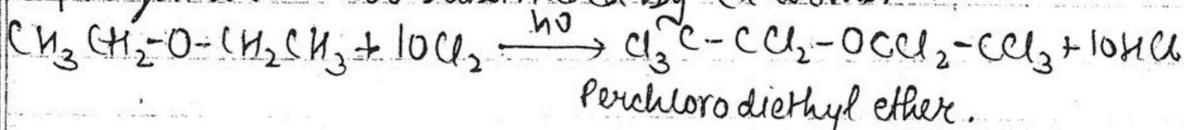

c. Reactions of Alkyl group.

1. Halogenation → Ethers react with Cl or Br in the dark to give substituted products.

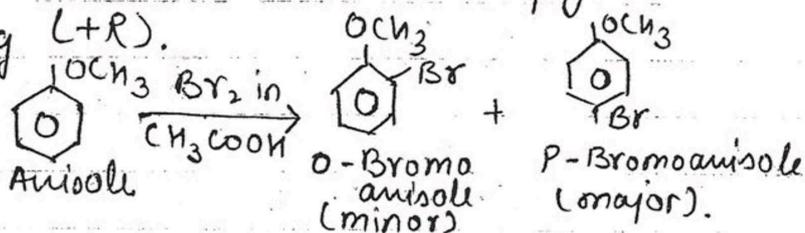

However, in the presence of light & excess of Cl all the hydrogen atoms are substituted by Cl atoms.

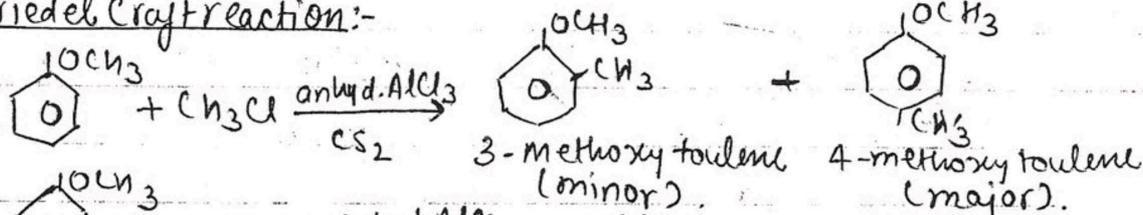

D. Ring Substitution in Aromatic Ethers :- Alkoxy gp. is ortho & para directing (L+R).

1. Halogenation :-

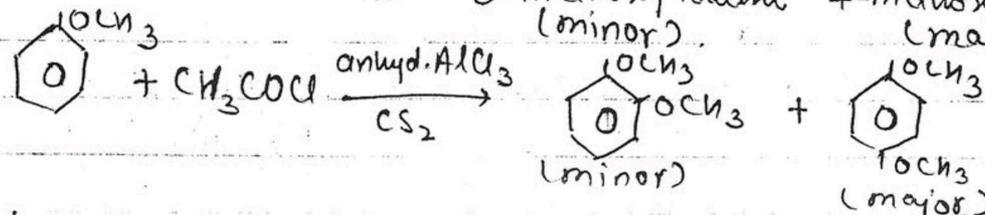

2. Friedel-Craft reaction :-

Alkylation

Acylation

3. Nitration :-
