

welcome to the first lecture on inverse trigonometric functions in the previous seven lectures we discussed trigonometric functions like  $\sin x$   $\cos x$   $\cot x$   $\tan x$   $\operatorname{cosec} x$  and  $\sec x$  from this lecture onwards we are going to define their inverses and we will also discuss the identities between these inverse functions let us take the case of  $\sin x$

so as we know from our previous lectures the  $\sin x$  function has a domain which is the set of all real numbers and the range is all numbers between minus one and plus one what this means is that if we take any real value  $x$  then  $\sin x$  will definitely belong to the closed interval minus one to plus one the next question is can we define the inverse function of the sine function

so by inverse function what i mean to say is that if we take any  $y$  belonging to minus one to plus one the question is when there exist a unique  $x$  will there exist a unique  $x$  belonging to  $\mathbb{R}$  such that  $\sin x$  is equal to this  $y$

so this is the basic question that we are asking

so lets obviously because  $\sin x$  as we know is a periodic function this is not true

so here on this slide i have plotted the graph of  $\sin x$  on the vertical axis  $x$  is on the horizontal axis and lets say that we have  $y$  equal to half and we are trying to find out all those  $x$  such that  $\sin x$  is equal to half

so what we do is we draw a horizontal line here which is parallel to the  $x$  axis and which is at a displacement of half on the positive side on the  $y$  axis and then what we see is that there are many values of  $x$  for example this value and this value here and this value this value of  $x$

so all these values of  $x$  are such that  $\sin x$  is equal to half and there are infinitely many actually

so this therefore from this we know that we cannot find a unique  $x$  such that  $\sin x$  is equal to half and therefore in general as of now it appears that it will be difficult to define the inverse of the sine function however we can still define its inverse for that we need to take up a smaller and simpler example

so on this slide we have a plot of the function  $f(x) = x^2$

so  $y = x^2$  is plotted on the vertical axis  $x$  is on the horizontal axis and this is the blue dotted curve is the curve for  $y = x^2$

so the function  $f$  is defined from the set of all real numbers to the set of all non negative real numbers which i denote by  $\mathbb{R}^+$  now as you can see here for any value of  $y$  in the range of this function  $f$

so let us take for example this is  $y = 1$

so for  $y = 1$  we see that there are two values of  $x$  one is  $x = 1$  and then there is another value of  $x$  which is  $x = -1$

so for both  $x = -1$  and  $x = 1$  we get  $y = 1$  and therefore again there is no unique  $x$  such that  $f(x) = x^2 = 1$  because for both these  $x = -1$  and  $x = 1$  we get  $y = 1$  and therefore there is no unique  $x$  which means that again to define the inverse of this function  $f(x) = x^2$  appears difficult

so one usual trick is that

so we try to restrict and define a new function  $f$  which is the same as the old function

so we still have  $f(x) = x^2$  but then we will restrict the domain of this function  $f$  from the set of all real numbers to a subset of the set of all real numbers

so let us say that we restrict this function  $f$  in this case to this following subset let us say that we restrict it to the set of all

so so we take this set which is

so so from  $0$  to all to infinity

so we say that we define a new function  $f'$  which is from  $r$  plus  
so  $r$  plus is essentially this interval from zero to infinity  
so we define a new function  $f'$  from  $r$  plus to  $r$  plus and  $f'$  of  $x$  is  
again  $x$  square right

so  $f'$  is again  $f' x$  is  $x$  square which is the same as what we had  
before its just that the domain now has been restricted from  $r$  to  $r$  plus but the  
advantage of doing this restriction is first of all that by restricting the  
domain from  $r$  to  $r$  plus we still still see that the entire range of the function  
is still the same

so earlier the range of this function the previous function  $f$  was  $r$  plus  
because  $f x$  equal to  $x$  square and since  $x$  square can only be non negative the  
range of the previous function was  $r$  plus even now when we restrict the domain  
of this function  $f$  from  $r$  to  $r$  plus even now the domain will still be  $r$  plus  
because all all non negative numbers will be in the range of this new function  $f'$   
prime

so what we see is that we have restricted the domain in such a way that the  
range of the function is still the same

so we are not changing the range of the function but the important thing that  
we have done here is that by doing this restriction of the domain now what we  
see is that

so i am plotting the graph of this function  $f'$  in red

so i essentially only consider the the graph of  $f x$  equal to  $x$  square only on  
the positive side of the horizontal axis

so this curve in red is the graph for the new function  $f'$  prime and now if we  
take any value of lets say we take

so this is  $y$  equal to one two three lets say four here

so if we take  $y$  equal to four and what we see is that with the restricted  
domain there is only one unique value of  $x$  which is  $x$  equal to 2 for which  $f'$   
prime  $x$  is equal to 4 in fact even for  $y$  equal to 1 for the restricted function  
the for the function  $f'$  prime with the restricted domain there will be only one  
unique solution which is  $x$  equal to plus one and this happens because we have  
restricted the domain of the function from  $r$  to  $r$  plus and therefore now there  
is uniqueness because we can take any other  $y$  we can take this  $y$  for example let  
us say this is some value of  $y$

so even for this wire this is the unique  $x$  this is the unique  $x$  such that  $f'$   
prime of  $x$  which is  $x$  square is equal to this  $y$  and therefore for this  
restricted function  $f'$  prime it is now possible to define the inverse  
meaningfully for for this  $f'$  prime function the inverse will be let us say  $g$   
which is from  $r$  plus to  $r$  plus and for any  $y$  ah belonging to  $r$  plus the inverse  
will be  $g$  of  $y$  will be equal to square root of  $y$  where this is the positive  
square root of  $y$

so this is how we define  $g$

so many times you will write  $g$  also as it is many times written as  $f'$  prime  
inverse

so we use this superscript on the ah on the name of the original function to  
whose inverse we are defining

so  $f'$  prime inverse or many times people do not even write like this they just  
write  $f'$  prime inverse is from  $r$  plus 2  $r$  plus and  $f'$  prime inverse of  $y$  for any  $y$   
belonging to the domain of  $f'$  prime  $f'$  sorry forgot a prime here  $f'$  prime inverse  
of  $y$  is equal to the positive square root of  $y$

so now we are going to use the same method of restricting the domain of the  
function such that the range does not get altered but then the the inverse  
should be meaningfully defined

so so the whole trick here is to restrict the domain of the function for

example even in this case if we if we lets say restrict the domain instead to be instead of  $r$  plus instead of  $r$  plus if we restrict the domain to let us say some interval minus 2 to plus 2 then this will not work because if we restrict the domain from minus two to plus two then the range of this function will only be from zero to

so let us say that we restrict it to minus two to plus two

so we restricted to minus two to plus two then the range of the function will be only from zero to four right whereas the range of the original function was the set of all non negative numbers and that is not the same as this range zero to 4 right

so this is not a meaningful restriction because we should try to restrict the domain of the function in such a way that the range does not get altered the range is still the same

so we will now use this technique to restrict the domain of trigonometric functions

so that we can define their inverse meaningfully

so we go back again to the  $y$  equal to sine  $x$  function and now we we know that the range of the sine  $x$  function is between minus one and plus one and if we see here if we restrict let us say the domain of the ah sine  $x$  function let us say we restrict it from minus  $\pi$  by 2 to plus  $\pi$  by 2.

so we restrict the domain of the sine  $x$  function to the interval to the closed interval minus  $\pi$  by two to plus  $\pi$  by two

so by this by doing this restriction we see that the curve for the restricted function will be the solid red curve which i am going to draw now

so it will be this

so this is the curve for the restricted sine  $x$  function where the domain has been restricted to minus  $\pi$  by 2 to plus  $\pi$  by 2 and as we can see here even after this restriction all the ah the possible values are there because if we try to follow this curve then for example here it is minus one and then as we go in this direction the values of  $\sin x$  go from minus one to zero continuously and then further if we go further towards ah further from zero to plus one and therefore even after this restriction the range the range of the sine  $x$  function is still minus one to plus one additionally what we also see is that if we take any value of  $y$  in the range minus one to plus one

so let us say we take this  $y$  here

so  $y$  equal to minus half

so if we take  $y$  equal to minus half then we see that there is only a unique value of  $x$  in this restricted domain such that  $\sin x$  is equal to minus half because as you can see in this restricted domain this sine  $x$  function when restricted to this domain is strictly monotonically increasing function of  $x$  and therefore this for any  $y$  that we take in this range minus one to plus one there will be a unique value of  $x$  a unique value of  $x$  in this interval such that  $\sin x$  will be equal to this  $y$

so for example we see here that for  $y$  equal to minus half this value of  $x$  is equal to

so this value of  $x$  is equal to minus 30 degrees or minus  $\pi$  over 6 and therefore we say that  $\sin$

so we have  $\sin$  of minus  $\pi$  by 6 is equal to minus half and from here then we write that  $\sin$  inverse of minus half is minus  $\pi$  by six

so now that we have restricted the domain of the sine function to the close interval between minus  $\pi$  by two and plus  $\pi$  by two we are in a position to define its inverse uniquely and meaningfully

so in this graph we are going to plot the sine inverse function whose domain

will be the interval the closed interval between minus one and plus one and the range will obviously be the closed interval between minus  $\pi$  by two and plus  $\pi$  by two here is a table of  $\sin x$  versus  $\sin^{-1} x$  values which will help us to plot this graph

so let's start with  $\sin^{-1}(-1)$

so we know that

so this is known to us that  $\sin(-\frac{\pi}{2}) = -1$

so from here we can say that  $\sin^{-1}(-1) = -\frac{\pi}{2}$

so  $\sin^{-1}(-1) = -\frac{\pi}{2}$

so  $\sin^{-1}(-1) = -\frac{\pi}{2}$

so  $\sin^{-1}(-1) = -\frac{\pi}{2}$  is here and  $\sin^{-1}(-1) = -\frac{\pi}{2}$  is over here

so we essentially have this point on the

so this is  $-1$  and this is  $-\frac{\pi}{2}$

so  $\sin^{-1}(-1) = -\frac{\pi}{2}$

so we basically have this point on the graph and then moving further ahead we have  $\sin^{-1}(-\frac{\sqrt{3}}{2})$

so  $\sin^{-1}(-\frac{\sqrt{3}}{2})$  which is  $\sin^{-1}(-\sin 60^\circ)$  is equal to  $-\frac{\pi}{3}$  and from there we can write that  $\sin^{-1}(-\frac{\sqrt{3}}{2}) = -\frac{\pi}{3}$

so  $\sin^{-1}(-\frac{\sqrt{3}}{2}) = -\frac{\pi}{3}$

so this is 4 units and  $-\frac{\sqrt{3}}{2}$  is around  $-0.866$

so that will be approximately somewhere here and then  $-\frac{\pi}{3}$

so this is  $-\frac{\pi}{3}$

so two thirds of this will be  $-\frac{\pi}{3}$  since this is six units it will be somewhere here and therefore this is the point on the graph that we get

so similarly from this graph we can also show that  $\sin^{-1}(-\frac{1}{\sqrt{2}}) = -\frac{\pi}{4}$  sorry  $\sin^{-1}(-\frac{1}{\sqrt{2}})$  will be equal to  $\sin^{-1}(-\frac{1}{\sqrt{2}})$  will be  $-\frac{\pi}{4}$  by four  $-\frac{1}{\sqrt{2}}$  is  $-\frac{\sqrt{2}}{2}$  which is somewhere here and  $-\frac{\pi}{4}$  is half of this which is somewhere there

so this and this is going to meet over here and then  $\sin^{-1}(-\frac{1}{2}) = -\frac{\pi}{6}$  which is  $-\frac{\pi}{6}$  and  $-\frac{1}{2}$  is here  $-\frac{\pi}{6}$  is one third of this thing which is over here

so we get another point like this and of course  $\sin^{-1}(0) = 0$  which is here will have a symmetrically similar thing on the  $\sin^{-1} x$  for positive values of  $x$

so will have this point for  $\sin^{-1}(1) = \frac{\pi}{2}$  because  $\sin^{-1}(\sin \frac{\pi}{2}) = \frac{\pi}{2}$  and then for  $\sin^{-1}(\frac{\sqrt{3}}{2}) = \frac{\pi}{3}$  which is over here

so this and then this will get us this point and similarly for  $\sin^{-1}(\frac{1}{2}) = \frac{\pi}{6}$  we are going to get this point here and then for  $\sin^{-1}(\frac{1}{\sqrt{2}}) = \frac{\pi}{4}$  we have this point here

so if we join all these all these dots we get the

so this dotted red curve is the graph for  $\sin^{-1} x$  similarly for  $\cos^{-1} x$  also  $\sin^{-1} x$  we see that if we do not restrict the domain of  $\cos$  function then again the reason is that because it is a periodic function what will happen is that with the domain as the whole real line we cannot define its inverse meaningfully because any value of  $y$  that we take in the range of this  $\cos$  function there will be many different values of  $x$  for which  $\cos x = y$  but we see that if we let's say restrict the  $\cos$  function just like the  $\sin$  function if we restrict the cosine function the domain of the cosine function to the interval from from

0 to  $\pi$

so we only consider from 0 to  $\pi$

so so 0 to  $\pi$  the closed interval between 0 to  $\pi$  if we restrict the cos function to this ah to this subset of the real line then the graph of the cos function will be like this and again what we see is that just like for the case of the sine function this the entire range is covered even if we restrict the domain to 0 to  $\pi$  the range of the cosine function when restricted to this 0 to  $\pi$  interval is still between 1 and minus 1 all values between 1 and minus 1 because this red curve is continuous between 1 and minus 1.

so we can start from one here and as we go along the curve we get we reach a value of zero at  $\pi$  by two and then further down we go all the way till minus one when  $x$  equal to  $\pi$

so the even by restricting the domain of the cos function to 0 to  $\pi$  the entire range is still the same further what we see is that if we take any value of  $y$  let us say we take  $y$  equal to let us say half over here

so so for  $y$  equal to half if we look at the original ah cos function whose domain was the entire real line then we will have many different values of  $x$  here and then another value here and another value here similarly another value here and here also and

so infinitely many values of  $x$  for which  $\cos x$  is equal to half but when we restrict the domain to zero to  $\pi$  what we will see is that there is only one value of  $x$  one unique value of  $x$  which is in this case in this example it is  $\pi$  by three or sixty degrees because  $\cos$  of sixty degrees is equal to half and therefore what we see is

so it is not just true for  $y$  equal to half we take any other  $y$  in the interval ah minus one to plus one which is the range of the cost function what we will see that there will always be a unique  $x$  in this in this restricted domain such that  $\cos$  of that  $x$  will be equal to this  $y$  and of course it is also visibly clear because as we can see this function cos function when restricted to this domain when restricted to 0 to 0 to  $\pi$  the graph is monotonically decreasing and therefore for any value of  $y$  that we take there will always be a unique  $x$  in this interval and therefore the inverse of the cos function can now be uniquely i mean meaningfully defined

so just like for the sine function we have the inverse of the cos function from minus one to plus one being the domain and the range is the closed interval 0 to  $\pi$  and again here we have a table of values

so just as we did for the sine function we start with

so we have  $\cos$  of  $\pi$  equal to minus one and therefore  $\cos$  inverse of minus one will be equal to  $y$

so  $\cos$  inverse of  $y$  equal to minus one is here will be equal to  $\pi$   $\pi$  is here

so we have this point on the graph ok and then let us take here

so here we have  $\cos$  of three  $\pi$  over four is equal to  $\cos$  of three  $\pi$  over four is equal to minus one upon square root of two and from here what we get is that  $\cos$  inverse of minus one over square root of two will be equal to three  $\pi$  over four

so minus one

so  $y$  equal to minus one over square root of two is ah somewhere here and three  $\pi$  by four is basically three quarters of

so this is nine units

so three quarters will be somewhere around six and three quarters of units three four five six and somewhere there

so the point that we have is this point on the graph and similarly ah when we go further ahead we see that for ah  $\cos x$  equal to minus half when  $x$  is equal to

two  $\pi$  by three and therefore  $\cos^{-1}$  of minus half

so  $\cos^{-1}$  of  $y$  equal to minus half

so  $y$  equal to minus half is here

so  $\cos^{-1}$  of minus half will be equal to two  $\pi$  by three which is two thirds of ah this whole range which is equal to six ah little square

so that comes over here

so so far we have gotten this part of the  $\cos^{-1}$  curve which i am showing with a dotted line and then further we know that  $\cos$  of  $\pi$  by two is zero and therefore  $\cos^{-1}$  of zero will be  $\pi$  by two

so  $\cos^{-1}$  of zero will be  $\pi$  by two is half of this entire range which will be somewhere here and then will have a similar ah symmetric you know curve about this line on the for positive values of  $y$

so for example for we know that  $\cos$  of  $0$  is  $1$  and therefore  $\cos^{-1}$  of  $1$  will be  $0$

so which is this point over here and let us take one more point

so  $\pi$  by three we know that  $\cos$  of sixty degrees which is  $\pi$  by three is equal to half right

so therefore  $\cos^{-1}$  of half will be  $\pi$  by three

so  $\cos^{-1}$  of  $y$  equal to half is here

so  $\cos^{-1}$  of  $y$  equal to half is  $\pi$  by 3  $\pi$  by 3 is here

so we have this point

so so the curve will look something like this something like that

so this is the curve for the  $\cos^{-1}$  function

so similarly we have the other trigonometric functions and everywhere we have the same problem that if we just look at the entire domain as we had defined in the previous lectures it will be difficult to define the inverse meaningfully and therefore we have to restrict the domain for example for the  $\tan$  function the domain is all real numbers except odd multiples of  $\pi$  by 2 the reason is that at odd multiples of  $\pi$  by 2 the  $\tan$  function becomes unbounded

so this is the graph of the  $\tan$  function on the  $x$  axis we have  $x$  the vertical axis is  $\tan$  of  $x$  and the blue dotted curve is the  $\tan x$  function and as we can see this is again a periodic function it repeats with  $\pi$  and therefore what we can do is that if we restrict the domain of the  $\tan$  function to the interval between minus  $\pi$  by two to plus  $\pi$  by two

so here we have to take the closed interval

so this will take sorry the open interval because

so this is the open interval the open intervals are denoted with a rounded bracket and the closed for the closed interval we take a square bracket

so if we restrict the domain to this open interval the reason for for taking the open interval is because the  $\tan$  function will become unbounded at minus  $\pi$  by two and plus  $\pi$  by two

so we have to avoid those two points

so all other points in between minus  $\pi$  by two and plus  $\pi$  by two will be the restricted domain of the  $\tan$  function and when we restrict the  $\tan$  function to that domain the curve for the restricted  $\tan$  function becomes i am showing it with the with the red curve

so the red curve as we can see now first of all the red curve is going to cover the entire range of the  $\tan$  function from minus infinity to plus infinity

so therefore even by restricting the domain of the  $\tan$  function to this open interval between minus  $\pi$  by 2 and plus  $\pi$  by 2 what we see is that the the range still remains the same as before which is the set of all real numbers the interesting thing however that happens is that if we take because we see that this red curve is a monotonically increasing curve right and therefore it is clear that if we take any value of  $y$  in the any value of  $y$  in the range of the

tan function

so any real value of  $y$  then what we will see is that there will be always a unique value of  $x$  in this interval minus  $\pi$  by two to plus  $\pi$  by two there will be unique value of  $x$  such that  $\tan$  of  $x$  will be equal to that  $y$

so therefore again for the  $\tan$  function it is clear that by restricting the domain to the open interval between minus  $\pi$  by 2 to plus  $\pi$  by 2 the inverse of the  $\tan$  function can be uniquely defined

so on this slide we again just like the sine and the cosine function we plot the graph of the inverse of the  $\tan$  function

so as we can see the domain of the  $\tan$  inverse function is the set of all real numbers the range of course is the open interval between minus  $\pi$  by two and plus  $\pi$  by two as shown here and let us try to plot the graph now

so as we can see from this table of values here that first of all  $\tan$  of 0 is 0

so we know that  $\tan$  of 0 is 0 and from that it follows that  $\tan$  inverse of zero will be equal to zero

so  $\tan$  inverse of  $y$  equal to zero

so  $\tan$  inverse of  $y$  equal to zero is equal to zero

so in this graph we have  $y$  is plotted on the horizontal axis and  $\tan$  inverse of  $y$  is plotted on the vertical axis

so  $y$  equal to zero is this point and  $\tan$  in  $\tan$  inverse of zero is also zero

so therefore we have this point on the graph of  $\tan$  inverse then we see that  $\tan$  of  $\pi$  by six is one over root three and therefore  $\tan$  inverse of one over root three will be equal to  $\pi$  by six

so  $\tan$  inverse of one over root three

so one over root three is ah should be somewhere over here

so this is  $y$  equal to one over root 3 and the value of the  $\tan$  inverse function and  $y$  equal to one over root 3 will be equal to  $\pi$  by 6 which is one third of this entire range which will be somewhere here will be somewhere there and then of course we know that  $\tan$  of  $\pi$  by 4 is 1 and since  $\tan$  of  $\tan$  of  $\pi$  by 4 equals 1 it follows that  $\tan$  inverse of 1 will be equal to  $\pi$  by 4

so  $\tan$  inverse of  $y$  equal to one will be  $\pi$  by four  $\pi$

so  $y$  equal to one is here and  $\pi$  by four is here

so we have this point on the on the graph right and similarly we can plot the other points also

so what we will end up getting is some curve like this but note that the value of the  $\tan$  inverse will as  $y$  goes to as the value of  $y$  goes to infinity as it becomes larger and larger the value of  $\tan$  inverse on the positive side for the positive values of  $y$  as  $y$  goes to infinity  $\tan$  inverse  $y$  will go to  $\pi$  by two but will never be equal to  $\pi$  by two it will converge as you can see this graph is going towards ah

so this is the line corresponding to the value of vertical axis being the value on the vertical axis equal to  $\pi$  by two

so this dotted curve will never go beyond this ah solid red line and similarly on the negative side also using this table we can draw the negative side the the curve for negative values of  $y$  and even here the curve that will get is something like this

so even

so here we have this line which is which corresponds to  $\tan$  inverse  $y$  which corresponds to minus  $\pi$  by 2 on the vertical axis and as  $y$  goes to minus infinity

so if as we go in this direction what happens is that the graph will go as you can see from here the graph will go nearer and nearer to this value of minus  $\pi$  by 2 but will never exceed that in fact  $\tan$  inverse  $y$  will never be equal to minus  $\pi$  by 2.

similarly for the cotangent function also that we have here the cotangent function the cotangent function is nothing but  $1/\tan x$

so which is an or we can even write it as  $\cos x / \sin x$

so cotangent  $x$  is equal to  $\cos x$  over sine of  $x$  and therefore what you will see is that whenever  $x$  is a multiple an integer multiple of  $\pi$  whenever  $x$  is an integer multiple of  $\pi$  sine of  $x$  is  $0$  and therefore cotangent of  $x$  for  $x$  being integer multiples of  $\pi$  is not well defined and that is clear from this graph where we have plotted  $x$  on the horizontal axis and  $\cot$  of  $x$  on the vertical axis we can see that at integer multiples of  $\pi$

so for example  $x$  equal to zero or  $x$  equal to  $\pi$  or two  $\pi$  we see that the graph goes to either plus infinity or minus infinity

so it becomes unbounded right and that is why when the domain of the cot function is defined it is defined like this

so we can for the domain we consider all real values except this set and this set is precisely what we mean by all integer multiples of  $\pi$

so this is the domain set of the chord function and of course the range will be the set of all real numbers because the chord function will take all real values between minus infinity and plus infinity and of course it is also periodic with  $\pi$

so  $\cot x$  is a periodic function with  $\pi$

so  $\cot x$  is equal to  $\cot$  of  $\pi$  plus  $x$  i mean if you just consider the same domain which is defined over here it will be defined difficult to define the inverse of the chord function any value of  $y$  that we take here let us say we take this  $y$

so this corresponds to  $y$  equal to three by two

so there will be many different values of  $x$  many different values of  $x$  for which  $\cot$  of  $x$  will be equal to this value three by two and therefore there is no unique  $x$  and hence with this domain the inverse of the cot function cannot be defined meaningfully and hence we again have to restrict the domain of the chord function

so what we do is we restrict the domain to this interval from  $0$  to  $\pi$

so we take this interval  $0$  to  $\pi$  but we cannot include the point  $0$  and  $\pi$  because the chord function is unbounded it is not well defined at these two end points

so therefore we take the open interval between  $0$  to  $\pi$  and restrict the domain of the chord function to this open interval when we restrict it what we see is that the curve of the chord function restricted to this open interval  $0$  to  $\pi$  now becomes what i am drawing with the red solid red curve here and it is very easy to see now that even after restricting the domain of the cot function to the open interval  $0$  to  $\pi$  what we see is that the range is still from minus infinity to plus infinity

so the range of the chord function is still the set of all real numbers even after restricting the domain from this to the open interval  $0$  to  $\pi$  and secondly it is very easy to also see that the solid curve here is monotonically decreasing and therefore if we take any  $y$  in the range of the chord function

so if we take any  $y$  let us take a  $y$  here

so we take this  $y$

so this  $y$  is ah minus three by two

so if we take any  $y$  there will be a unique  $x$  which is here which will lie in this restricted domain of the chord function such that  $\cot$  of  $x$  will be equal to this  $y$

so this will be true for any value of  $y$  that you take and that is very much clear also because this chord function is a continuous function in this it is a continuous function in this restricted domain and additionally it is

monotonically decreasing and therefore by restricting the chord function to this domain we should be able to define its inverse meaningfully

so we again try to plot the graph for the cot inverse function whose domain will be the set of all real numbers and the range will be now the restricted domain of the chord function which is the open interval between zero to  $\pi$  now we know that let us start from here we know that cot of  $\pi$  by two is equal to zero and therefore cot inverse of zero will be equal to  $\pi$  by two

so cot inverse of y equal to zero

so y equal to zero is here will be equal to  $\pi$  by two

so  $\pi$  by two is here

so so we get this point on the on the graph of cot inverse y

so here in the graph we have y is plotted on the horizontal axis and the corresponding cot inverse of y will be plotted on the vertical axis similarly we have cot of  $\pi$  over three equals one over square root of three and therefore cot inverse of one over square root of three will be equal to  $\pi$  over three

so cot inverse of one over square root of three will be somewhere there and  $\pi$  over three is somewhere here

so it will be somewhere there and then as we

so will get this point here

so this is

so this was  $\pi$  over two this is equal to  $\pi$  over three and then as we increase y to more positive values

so we are going in this direction here

so so for example cot inverse of square root of 3 will be  $\pi$  by 6

so as we increase y what we will see is that cot inverse will decrease and go towards zero

so cot inverse

so from here from the table what we see is that cot inverse of square root of three is equal to  $\pi$  by six

so square root of three will be somewhere here and  $\pi$  by 6 is somewhere

so  $\pi$  this is this is  $\pi$  by 6.

so we get this point on the curve right

so essentially what we have is

so far we have plotted and it will go like this but the value as

so as y goes to infinity cot inverse y will go towards zero but it will never be equal to zero right and then for the negative values of y what we will see is that will have a similar type of curve

so and which we can be drawn by looking at the negative values of cot x

so for example from here what we will see is that cot inverse of minus 1 for example will be equal to  $\frac{3\pi}{4}$

so minus one is over here and  $\frac{3\pi}{4}$  will be

so this is six units

so  $\frac{3\pi}{4}$  will be four and a half units right

so it will be somewhere there somewhere over here

so this is y equal to minus one and this value here is  $\frac{3\pi}{4}$  and then ah for on for for further even more negative values what we will see is that the value of the cot inverse function will go towards  $\pi$

so now we are going in this direction

so as we make the value of

so this is the value of y on in this column as y becomes more and more negative so from minus one to minus square root of three as y becomes more negative the value of ah this x is going towards  $\pi$

so what we will have is

so this is  $\pi$   
so this is  $\pi$   
so this curve the dotted curve will go something like this  
so we finally have the red dotted curve for  $\cot^{-1} y$   
so as  $y$  becomes more and more negative  $\cot^{-1} y$  will tend towards  $\pi$  but will always be less than  $\pi$  in fact it will never be equal to  $\pi$  the next function is  $\operatorname{cosec} x$

so the cosecant function  $\operatorname{cosec} x$  is as we know defined as  $1/\sin x$  and it is also a periodic function trigonometric function and because it is  $1/\sin x$  it will not be meaningfully defined whenever  $\sin x$  is equal to zero

so therefore whenever  $x$  is an integer multiple of  $\pi$   $\operatorname{cosec} x$  is not meaningfully defined and therefore the domain of the cosecant function is the set of all real numbers except integer multiples of  $\pi$

so that is the domain of  $\operatorname{cosec} x$  and for the range what we see is that because  $\operatorname{cosec} x$  is  $1/\sin x$  and since the range of  $\sin x$  is the all values between minus 1 and plus 1 what will happen is that  $1/\sin x$  will take all values outside the interval minus 1 to plus 1.

so and that is very much clear from this graph where we have  $x$  on the horizontal axis and we have  $\operatorname{cosec} x$  on the vertical axis as we can see the blue dotted curve will never take any value between minus one and plus one and this is because it is  $1/\sin x$  and  $\sin x$  takes values between minus one and plus one and therefore the range of the cosecant function is the set of all real numbers except this range minus 1 to plus 1 and therefore now with because it is still periodic as we can see it is still a periodic function  $\operatorname{cosec} x$  is a periodic function of  $x$  if we have this as the domain we still cannot define the inverse of the cosecant function meaningfully and therefore we need to restrict the domain of the cosecant function as we have done for the other previous trigonometric functions

so in this case one possible choice is that we consider the interval minus  $\pi/2$  to plus  $\pi/2$  except the point 0.

so we are going to restrict the domain of the cosecant function to the closed interval minus  $\pi/2$  to plus  $\pi/2$  but except the point zero because at  $x$  equal to zero  $\operatorname{cosec} x$  is not meaningfully defined because it becomes unbounded

so by now by restricting the cosecant function to this set or this subset of the real line the restricted cosecant function the graph of the restricted cosecant function will look something like this

so i am drawing it with the solid red curve here and as we can see even by restricting the domain of the cosecant function to this interval we see that all the range of the restricted cosecant function is still the same thing which is all real values except minus one to plus one because it cannot take any value between minus one to plus one anyways but apart from this range of values it does take all other possible values because for the interval between minus  $\pi/2$  and 0 if we go if we start from here

so this this value over here is this is minus one and if we go like this then we see that the curve is continuous and starting from minus one it goes all the way till minus infinity and similarly if we start from here then this value is plus one and if we go like this the curve is again continuous and it goes from the value goes from one to infinity

so we have values going from one to infinity and then from minus 1 to minus infinity which is basically the same range

so even by restricting the domain to this subset of the real line the range of the cosecant function is still the same it still remains the same and additionally ah what we also see is that if we take any  $y$

so let us take any  $y$  in this range set

so let us say that we take this particular value of  $y$  here

so this value of  $y$  corresponds to two point five

so so this is ah

so this is  $y$  equal to two point five

so for this ah what we see is that there is exactly one unique value of  $x$  which is here such that cosecant of this  $x$  this value is equal to 2.

5 and of course this value lies in the restricted domain if we had not restricted the domain that there would have been many other values for example this value of  $x$  or for example this value of  $x$  or this value of  $x$

so there would have been infinitely many different other  $x$  values of  $x$  such that cosecant of  $x$  would have been 2.

5 and therefore there is no unique value as such but when we restrict the domain to this interval we see that for any value of  $y$  in this range there will always be a unique  $x$  there always be a unique  $x$  in the restricted domain such that cosecant of that  $x$  will be equal to  $y$  that value of  $y$  and therefore again by doing this restriction we should be able to meaningfully define the inverse of the cosecant function which i have will try to plot it in this slide here and this can be just done just similar to what we have been doing for the other for the other functions and i will quickly show it to you how it looks

so this is how it looks

so again using the table we can plot

so the what we have is we have  $y$  on the horizontal axis and cosecant inverse of  $y$  on the vertical axis the domain of the cosecant inverse function is will be the range of the cosecant function

so the domain of the cosecant inverse function is all real numbers except the interval minus one to plus one and the range of the cosecant inverse function will be the modified or the restricted domain of the cosecant function that we saw on the previous slide which is the closed interval minus  $\pi$  by two to plus  $\pi$  by two except the point zero and then again using this table of values we through the red curve here and here is what is the graph of the cosecant inverse function and as we can see ah with as  $y$  becomes more and more positive the value of cosecant inverse will go towards this value of zero

so this curve red curve here will always be above the horizontal axis on the positive side and for negative values of  $y$  the red curve will always be below the horizontal axis

so i mean this part of the curve and similarly the secant function will have a similar problem and for the secant function also we need to to define the inverse of the secant function meaningfully just like the other trigonometric functions we have to also restrict its domain because ah secant of  $x$  is equal to one over cos of  $x$  and we know that cos of  $x$  is zero whenever  $x$  is a odd multiple of  $\pi$  by two

so therefore the domain set of the secant function is defined to be all the set of all real numbers except odd multiples of  $\pi$  by two because at odd multiples of  $\pi$  by two secant of  $x$  is not well defined as can also be seen from this graph where we have  $x$  on the horizontal axis and secant of  $x$  on the vertical axis and what we see is again the secant function is also periodic and the range as we can see is that because secant of  $x$  is one over cos  $x$  and cos  $x$  is between minus one and plus one

so what happens is that the range of the secant function is the entire real line which is the entire vertical axis here except this interval between minus

one and plus one

so that is this range and just like the other trigonometric functions we again have the same problem that because secant is function is periodic with this domain with this as a domain we cannot define the inverse meaningfully and therefore we need to restrict the domain of the secant function also

so what we do is that we restrict the domain between  $0$  and  $\pi$

so we take the restricted domain to be the closed interval between zero to  $\pi$  but as we can see we have to we should not have the point  $x$  equal to  $\pi/2$  and the reason is because at  $x$  equal to  $\pi/2$  secant of  $x$  is unbounded it is not well defined right

so the modified domain will be  $0$  to  $\pi$  interval except the point  $\pi/2$  and the graph of the secant function will then be what i am drawing with the red curve

so this will be the graph of the secant function when the domain is restricted to this interval  $x$  at  $\pi/2$  and as we can see the entire the range even after this restriction of the domain is still the same it is still all real values except the interval minus 1 to plus 1 right

so all values are there except minus 1 to plus 1 and also what we see is that for if we take any value of  $y$  then we can always

so if we take any value of  $y$  there will be a unique value of  $x$  such that secant of  $x$  is equal to  $y$  and that value of  $x$  will be in this interval and therefore by this restriction the we can meaningfully define the inverse of the secant function which i am defining here

so on this graph we have  $y$  on the horizontal axis and secant inverse is plotted on the vertical axis and as we can see we are again going to make the use of the table values for  $x$  versus secant  $x$  the secant inverse function is defined from the this will be the domain which is basically the range of the secant function and the range of the secant inverse function will be the restricted domain of the secant function which is  $0$  to  $\pi$  except the point  $\pi/2$ .

this is what we get

so in this lecture we had we had initially tried to define the inverse of the trigonometric functions but we immediately ran into a problem because the the trigonometric functions are ah most all of them are periodic and therefore with the with their normal definition of their domains it is difficult to define their inverses meaningfully and but then what we saw was that if we restrict the domain of these functions we can define their inverses meaningfully

so in the next class we will take all these will try to define and prove lot of identities and relations between these 6 inverse trigonometric functions that we defined in today's class thank you you
