

welcome students we have finished most of the theory regarding definite integrals today we are going to learn miscellaneous examples which will help you in solving complicated problems of competitive exams let us take an example on area

so the area is defined by a set in cartesian plane  $4x - 1$

so the first step to solve this problem is we need to identify the region

so let us first find out what is represented by  $y^2 \leq 2x$  to realize that we have to plot first this equation which you know it is a parabola whose vertex is  $(0, 0)$  and axis is x axis

so you get this is  $y^2 = 2x$  now we need to find out which region which region is represented by  $y^2 \leq 2x$

so if you take any point outside the parabola maybe here here here or here

so let us take  $(0, 1)$  and see

so if  $x$  is  $0$  you get  $0$  into  $2$  that is  $0$  and this side lhs you get  $1$  which is strictly  $1$  is strictly greater than  $0$

so the inequality is not satisfied similarly you can check it for this point say this point is this point is  $(-1, 0)$

so  $2x$  will be  $-2$  and  $y^2$  will be  $0$  at  $(-1, 0)$

so again you can see that the inequality that you get is this similarly for this point also

so if you take any point above parabola or on the negative side of x axis are below this parabola

so all these points are outside the region

so if you take any point inside the parabola you see that this inequality will be satisfied  $y^2 \leq 2x$

so  $y^2 \leq 2x$  is this shaded area

so this shaded area is  $y^2 \leq 2x$  let us see what region is represented by  $y^2 \geq 4x - 1$

so for that we have to plot first the line  $y = 4x - 1$

so let us plot  $y = 4x - 1$  and then we try to realize what is this region  $y \geq 4x - 1$

so for that first let us plot the line  $x, y$  this is  $(0, 1)$  and if  $x$  is  $0$   $y$  is  $-1$

so this is  $(0, -1)$

so this is the line  $y = 4x - 1$  now if you take any point

above  $x$  axis say on  $y$  axis above  $x$  axis on  $y$  axis say this is  $(0, 1)$

so  $4x - 1$  will be  $-1$  and  $y$  is  $1$

so  $1$  is greater than  $-1$

so then equality is true now if you take any point below this line say you take  $(0, -2)$

so  $4x - 1$  at  $x = 0$  is again  $-1$  and  $y$  is  $-2$

so  $-2$  is lesser than  $-1$

so the inequality is not satisfied

so if you take any point above this above this line that means this region the inequality is satisfied

so this  $y \geq 4x - 1$  is this red  $y \leq 4x - 1$  is this shaded area now let us plot both the curves on one cartesian plane

so that we can realize which area we are supposed to compute

so we need to now draw  $y^2 = 2x$  and  $y = 4x - 1$  on one cartesian plane

so  $y^2 = 2x$  is this and  $y = 4x - 1$  is

so your  $y^2 \leq 2x$  is area shaded by green color and  $y \geq 4x - 1$  is area shaded by red color

so the common area that satisfies that is satisfied by both the inequalities is this area

so we are supposed to find out this area for that we need to find out the point of intersection of both the curves

so we need to solve both the curves

so  $y$  equals to four  $y$  square equals to two  $x$  four  $x$  is  $y$  square by two minus one

so  $y$  values will be

so we get 1 and minus 1 by 2

so this is  $y$  equals to minus half and this is  $y$  equals to one

so the area required if you integrate in the direction of  $y$

so you have to divide this area by smallest thin strips horizontal strips

so if say this is  $d y$  width of one strip

so length of the strip will be  $y$  value from this line minus  $y$  value from parabola

so length of the strip is  $y$  plus 1 by 4 minus  $y$  square by 2 this is the length and divide the width

so this is your elementary area and if you integrate it from minus half to one you get the required area

so let us integrate this to find out the final required area

so this is one by four this is equal to i get this

so minus nine by thirty two

so this is your final answer now let us take another example we need to find out the area enclosed by

so find out area enclosed by above to to curves and the lines  $x$  equals to zero and  $x$  equals to  $\pi$  by two

so let us plot  $y$  equals to  $\sin x$  plus  $\cos x$  first

so you just try to find out see what is the value of  $y$  zero  $y$  zero is 1  $y$   $\pi$  by 2 is also 1 and if you find out the derivative you see that it is  $\cos x$  minus  $\sin x$

so to find out whether it is  $y$  dash is positive or negative we need to just this is a rough work not actual plot

so you need to plot  $\cos$  and  $\sin$  both this  $\pi$  by four

so graph of  $\sin x$  from 0 to  $x$  equals to 0 from 0 to  $\pi$  by 2 is this and graph of  $\cos x$  plot will be like this

so the values there they have same values at  $\pi$  by four

so you can see that this is  $\cos x$  and this one is  $\sin x$  black one is  $\sin x$  and red one is  $\cos x$

so you can see that  $\cos x$  dominates  $\sin x$  between zero and  $\pi$  by four

so this will be positive in this interval and  $y$  dash will be  $y$  dash that means  $y$  dash is this

so  $y$  dash will be negative when  $\sin x$  dominates  $\cos x$

so this will be negative in this interval and  $y$  dash at  $\pi$  by four is zero

so the plot of this  $\pi$  by four is  $\pi$  by two this is zero if this is one one unit on  $y$  axis

so at zero the value is 1 at 0 the value of this is 1 and at  $\pi$  by 2 the value is 1 and at  $\pi$  by 4  $y$  value is  $1$  by  $\sqrt{2}$   $1$  by  $\sqrt{2}$  by  $\sqrt{2}$  that is  $\sqrt{2}$  which is greater than 1 and

so somewhere here if  $i$  represent root two this is root two say

so  $y$  is increasing  $y$  dash is positive from 0 to 4

so  $y$  is increasing

so we will get this curve and at  $\pi$  by 4 it is 0

so the horizontal any the horizontal line which passes through  $\pi$  by 4 comma  $\sqrt{2}$  will be tangent and after that since  $y$  dash is less than 0 the curve will

be decreasing at it reach here

so you have this shape of  $y$  equals to  $\sin x$  plus  $\cos x$  we get this shape this shape let us plot this curve also diff on a separate cartesian plane then we will combine it let us plot  $y$  equals to  $\cos x$  minus  $\sin x$  on a separate cartesian plane

so let us plot  $\cos$  and  $\sin$  again because we need to refer that this  $\pi$  by 4 this is  $\pi$  by 2 this is  $0$

so  $\cos 0$  is 1 because  $\pi$  by 4 is 1 by root 2  $\cos \pi$  by 2 is  $0$

so this is  $\cos x$  and say this is your  $\sin x$  this is your  $\sin x$

so this is  $\sin x$  this  $\cos x$  since modulus is there to open this we need to know where  $\cos x$  dominates  $\sin x$  and where  $\sin x$  dominates  $\cos x$

so  $y$  dash is  $\cos x$  minus  $\sin x$  because  $\cos x$  dominant  $\sin x$  in the interval zero  $\pi$  by four and if you compute  $y$  dash you get  $\sin x$  minus  $\cos x$  because  $\sin$  and  $\cos$  both are positive

so this will be negative in this interval similarly for the other interval that means from  $\pi$  by 4 to  $\pi$  by 2  $y$  is minus of because  $\sin x$  dominates  $\cos x$

so we get minus of  $\cos x$  minus  $\sin x$  and  $y$  dash will be  $\sin x$  plus  $\cos x$  which is always positive in this interval

so how this curve this curve will look like ah at  $y 0$  it is again 1 at  $y$  by four it is zero and at  $y \pi$  by two it is from you can put the values of  $x$  here and see what is  $y$

so  $y \pi$  by two it is again one

so if this is this  $x$  equals to zero this is  $x$  goes to  $\pi$  by two and this is  $x$  equals to  $\pi$  by four

so from zero to  $\pi$  by four  $y$  dash is negative

so  $y$  is decreasing and  $y$  value at zero is one

so and  $\pi$  by four it is zero

so it is decreasing  $y$  is decreasing because  $y$  dash is less than  $0$  from  $\pi$  by 4 to  $\pi$  by 2  $y$  dash is positive

so it is increasing and  $\pi$  by 4 is  $0$  and  $\pi$  by 2 it is 1 this one

so you get this curve now let us plot both the curves on a single cartesian plane

so that we can realize what is the area

so  $y$  equals to  $\sin x$  plus  $\cos x$  and  $y$  equals to mod of  $\cos x$  minus  $\sin x$  this  $y$  axis is  $x$  axis this is this is one unit is  $\pi$  by four is zero this is  $\pi$  by two

so and this is somewhere is this is root two

so  $\sin x$  plus  $\cos x$  is this curve we have seen and mod of  $\cos x$  minus  $\sin x$  is this curve

so this is drawn by black color and this one is drawn by blue color

so the required area is this this is your required area

so to find out this area we need to break it in two parts because if you draw vertical strips thin rectangles say of  $d x$  width

so you can see that for this portion which lies between zero and  $\pi$  by four it starts from one curve when it is it ends uh it finishes on  $y$  equals to  $\sin x$  plus  $\cos x$  and for this portion it starts with another portion of the curve which is going by different equation

so we need to break it in two parts

so total area required will be elementary area from zero to  $\pi$  by four

so elementary area is  $\sin x$  plus  $\cos x$  minus this which is  $\cos x$  minus  $\sin x$   $d x$  plus from  $\pi$  by four to  $\pi$  by two  $d x$  elementary area is this into  $d x$  and what is this is  $\sin x$  plus  $\cos x$  minus this equation of this curve is minus of minus  $\cos x$  plus  $\sin x$

so we get zero to  $\pi$  by four  $2 \sin x d x$  plus  $\pi$  by four  $2 \pi$  by two  $2$

$\cos x dx$  let us integrate it ok

so you got this the integration of this is  $-\cos x$  from  $0$  to  $\pi$  by  $4$  plus integration of this is  $\sin x$  from  $\frac{\pi}{4}$  to  $\frac{3\pi}{4}$  by  $2$  we get by putting the upper and lower limits we get upper limit is this and lower limit will give you by root 2.

so total value is four times four times one minus one by root two

so required area is four times one minus one by root two

so there is one important point to notice in this example if you see the region this region can be divided into two portions and this region which i have shaded now even with blue color and this one by green

so they are symmetrical

so instead of computing both the areas separately you can just compute this and twice of this will give you the required area fine let us take another example find all possible values of  $b$

so that area of the bounded region enclosed between parabolas  $y$  equals to  $x$  minus  $b$   $x$  square and  $y$  equals to  $x$  square by  $b$  is maximum where it is given that  $b$  is positive

so you can see that this is a very simple curve  $y$  equals to one by  $b$  square is a parabola whose vertex is zero and axis is  $y$  axis  $y$  equals to one by  $b$   $x$  square

so  $b$  is for since  $b$  is positive if  $b$  is negative it would have been inverted

so this is a parabola let us plot  $y$  equals to  $x$  minus  $b$   $x$  square this we can write as  $x$  minus  $b$  if we take common we get  $x$  square minus  $x$  by  $b$  which we can write as  $x$  square minus  $x$  by  $b$  square

so therefore this can be written as  $x$  square minus  $x$  by  $b$  square

so  $y$  minus one by  $b$  square is equal to  $x$  square minus  $x$  by  $b$  square this

so this equation is of this kind  $b$  is positive

so this parabola is inverted whose vertex is at one by  $2b$  comma one by  $4b$  and it passes through you can see that  $x$  equals to zero  $y$  equals to zero and  $x$  equals to  $1$  by  $b$   $y$   $0$

so this is inverted parabola whose axis is  $x$  equals to  $2$  by  $b$  and vertex is one by  $2b$  one by  $4b$  now let us plot both the parabolas on a single cartesian plane this is your  $y$  equals to  $x$  square by  $b$  and the other one is this

so your area that is enclosed between them is this one

so we need to find out this point of intersection of both

so let us solve both the equations

so we get  $x$

so  $x$  is therefore zero if you solve this you get  $x$  equals to zero and  $x$  equals to  $b$  by  $1$  plus  $b$  square

so this this is  $x$  equals to  $b$  by  $1$  plus  $b$  square

so the area required is elementary area

so elementary area is  $x$  minus  $b$   $x$  square minus  $x$  square by  $b$  into  $dx$   $x$  goes from  $0$  to  $b$  by  $1$  plus  $b$  square let us integrate this

so so required area  $x$  square by  $2$  minus  $b$  by  $3$   $x$  cube minus  $x$  cube by  $3$   $b$   $0$  to  $b$  upon  $1$  plus  $b$  square this is equal to  $b$  square by  $2$  minus whole cube minus  $b$  cube by  $3$   $b$  one plus  $b$  square cube minus this  $b$  square

so if we take common plus  $b$  square cube we get  $b$  square upon one by three plus  $b$  square cube  $b$  square by one plus one by  $b$  square by three into one plus  $b$  square cube is common

so we get one plus  $b$  square

so value of this is required area is  $b$  square by  $2$  into  $1$  plus  $b$  square square minus this cubic will be cancelled and by this one

so you get square here

so  $b$  square upon  $3$  plus  $b$  square square this is equal to  $3$  minus  $2$  by  $6$   $b$  square upon  $1$  plus  $b$  square square

so required area is  $b^2$  by six one plus  $b^2$  by whole square  
 so we have computed the required area now the question says that find ah for  
 which value of b the area is maximum  
 so let us compute that  
 so your area is  $ah$   $b^2$  by one plus  $b^2$  square one by six  
 so b is positive it is given  
 so for which value of b area is maximum for that let us differentiate this we  
 get this by applying rules of differentiation  
 so one plus  $b^2$  is common here  
 so what we get is  $2b$  plus  $2b^3$  minus  $4b^3$   
 so we get one by six one upon one plus  $b^2$  power four  $2b$  minus  $2b^3$   
 so finally we get  $1$  by  $3$   $b^3$  one minus  $b^2$  by one plus  $b^2$  this is  
 cancel it is cubic not four cube  
 so we have got  $b$  a by d b as one by three  $b$  one minus  $b^2$  upon one plus  $b^2$   
 square cubic now d a by d b equals to zero will give you the required points  
 where this can be maximum or minimum  
 so we get  $b$  equals to zero  $b$  equals to minus one  $b$  equals to plus one  
 so these two values we have to ignore because b is positive  
 so the only possible value that is allowed is of b that at which we are we are  
 supposed to compute maximum minimize  $b$  equals to one now how to find out maximum  
 so we are not going to find out the double derivative let us see how to find  
 out where the x whether the area is maximum or minimum at  $b$  equals to one  
 so d a by d b d a by d b is one by three  $b$  one minus  $b^2$  by one plus  $b^2$   
 square cubic  
 so and you can see that if b is greater than one then d a by d b is negative  
 and once b is less than one between zero and one d a by d b is positive  
 so a increases when b increases and a decreases when a takes value greater than  
 one  
 so if you plot this around b if this is the area you plot the area  
 so b these one this is b  
 so when b is greater than one d a by d b is less than zero  
 so this is decreasing and when b is less than one it is increasing  
 so at one at  $b$  equals to one area is maximum with this we finish some examples  
 on area let us see some more examples on definite integrals miscellaneous from  
 different computational exams this is the problem it seems to be a very  
 complicated problem on definite integrals but if you apply certain properties of  
 definite integral it becomes very simple  
 so we know that  $x \log n$  power n is  $n \log m$   
 so we get this here you can write this as  $6$  minus  $x$  whole square  
 so this will give us and  $2$  gets cancelled we get  
 so finally we got this integral and see that we are going to use this property  
 of definite integral which says that this value is equal to  $a$  plus  $b$  minus  $x$  dx  
 this value of the integral is same as this value now apply this  
 so you get  $2$  to  $4$  log of a is  $2$  b is  $4$   
 so you get  $6$  minus  $x$   $6$  minus  $x$  dx by log x will be replaced by  $6$  minus  $x$  plus  
 log  $6$  minus  $6$  minus  $x$   
 so i is therefore two to four log six minus  $x$  d x by log six minus  $x$  plus log x  
 so this you can see that this if you say this is 1 and you say this is 2  
 so both represents our initial integral and if we add it the integrand will  
 become 1 because numerator will be log x plus log  $6$  minus  $x$  and denominator will  
 be log x plus log  $6$  minus  $x$   
 so both will get cancelled  
 so we will add it and we get  $2$  i equals to  $2$  to  $4$  log x plus log six minus  $x$  by  
 log x plus log six minus  $x$  d x and this will get cancelled

so we get  $\int dx$  which is  $4x - 2x^2$  is this two  
 so value of  $i$  is there for one now let us take another example  $x^2 \cos x$   
 $\int_0^{\pi} x^2 \cos x dx$   
 so let us break it in two parts  $\int_0^{\pi} x^2 \cos x dx$  is equal to  
 so since this integral is of the kind  $\int_a^b f(x) dx$   
 so we need to find out whether it is even or odd function  
 so this function is even function because if you replace  $x$  by  $-\pi - x$  you get  $x^2 \cos x$  and  $\cos$  of  $-\pi - x$  is  $-\cos x$   
 so you get twice of  $0$  to  $\pi$  by  $2x^2 \cos x dx$  and if you see this function if you put  $-\pi - x$  here you get  $\pi + x$  by  $\pi - x$  is  $\cos$  of  $-\pi - x$   
 so  $\cos$  of  $-\pi - x$  will be  $-\cos x$  and here you get plus and minus if you put and by using the property of  $\log$  you will see that you get a minus sign if you replace  $x$  by  $-\pi - x$  throughout this integral integrand you get a minus sign outside  
 so this is an odd function therefore by using the property of the definite integrals you will get zero  
 so to see it carefully let us do that  
 so you want to find out whether it is even or odd  
 so if this is  $\int_0^{\pi} x^2 \cos x dx$  of  $-\pi - x$  is  $\log$  of  $\pi + x$  by  $\pi - x$   $\cos$  of  $-\pi - x$  by using the property of  $\cos x$  and  $\log$  this can be written as  $-\cos x$  which is  
 so it this is an odd function therefore  $\int_{-\pi}^{\pi} x^2 \cos x dx$  will be  $0$   
 so your  
 so your integral becomes finally you got this expression this is your value of the original integral twice of  $x^2 \cos x dx$  this will be equal to  
 so you need to integrate it by parts first function this is second function this function integral of second is  $\sin x$  this is this is zero  
 so twice of zero to  $\pi$  by two we got  
 so first function into integral of second zero to  $\pi$  by two minus zero to  $\pi$  by two  $2x^2 \sin x dx$  to  $\pi$  by four minus zero minus first function into integral of second is  $-\cos x$   $0$  to  $\pi$  by two minus minus plus  $0$  to  $\pi$  by two differential of first is  $2$  and  $-\cos x dx$   
 so this will be  $0$  at  $\pi$  by two  $\cos \pi$  by two  $0$  at  $0$  this is  $0$  because of this  
 so you get  $2 \pi$  by four minus two integral of  $\cos x$  is  $\sin x$   
 so you get zero to  $\pi$  by two this is  $2 \pi$  by four minus  $2$   
 so final answer is  $\frac{1}{2} \pi^2$  here one  $\pi^2$  you get  $\pi^2$   $\pi^2$   
 so final answer is  $\frac{1}{2} \pi^2 - 4$  let us take another example under root  $\log$   $\log$  under root  $\log 2$  by  $2$  under root  $\log 3$   $x \sin^2 x$   $\sin x$  square by  $\sin x$  square plus  $\sin \log 6$  minus  $x$  square  $dx$   
 so since you see that  $x$  square is there and  $x$  is here in the integrand  
 so if you take  $x$  square equals to  $t$  that will ease our computation and limits will be freed from square  
 so immediately you get  $x$  is if you put  $x$  is under root  $\log 2$  you get  $\log 2$  as well of  $t$  and upper limit will be  $t$  equals to  $\log 3$   $2x dx$  will be  $dt$   
 so this  $x$  you can combine with  $dx$  it will replace by  $\frac{1}{2} dt$   $\sin x$  square is  $\sin t$  by  $\sin t$  plus  $\sin$  of  $\log 6$  minus  $t$   
 so your integral is  $\frac{1}{2} \int_{\log 2}^{\log 3} \sin^2 t dt$  by  $\sin t$  plus  $\sin \log 6$  minus  $t$   $\log 6$  minus  $t$  now by applying the properties of definite integral which says that  $\int_a^b f(x) dx$  is same as  $\int_a^b f(a+x) dx$   
 so we get  $\log 2$  to  $\log 3$   $\sin$  of  $\ln 2$  plus  $\ln 3$  will be  $\ln 6$   
 so  $\log 2$  plus  $\log 3$  will be  $\log 6$   
 so  $\log 6$  minus  $t$   $t$  by  $\sin$  six  $\sin \log 6$  minus  $t$  plus here  $t$  is replaced by  $\log 6$  minus  $t$

so you will get  $\sin t$  from this term

so you can see that if you add these two integrals

so numerator and denominator will be same

so they get cancelled

so you get  $\sin t$  plus  $\sin \log 6$  minus  $t$  by  $\sin \log 6$  minus  $t$  plus  $\sin t$   
 $d t$

so this get cancelled and you get two  $i$  equals to one by two  $\log 2$  was two  
was missing here  $\log 3 d t$  this is equal to  $\frac{1}{2} \log 3$  minus  $\log 2$  which  
is equal to

so therefore  $i$  is one by four  $\log 3$  by two we have seen certain  
miscellaneous examples on definite integrals on area and definite ah other kind  
of definite integrals

so in our next class we shall continue with ah miscellaneous examples and see  
how to approach such complicated problems thank you you
